The Australian Antarctic Division produces the two serials *ANARE Reports* and *ANARE Research Notes*. Anyone who has participated in research that was supported by the AAD is invited to publish through these series. Both are published only in electronic form except in special circumstances. Access to the electronic publications is free through the Australian Antarctic Division website at www.antdiv.gov.au

The *ANARE Reports* series is peer reviewed, which is appropriate for manuscripts that are considered too lengthy or detailed for journal publication.

The *ANARE Research Notes* series is not peer reviewed, allowing for more rapid publication, and is appropriate for manuscripts that have a practical field application such as manuals, identification keys, datasets and atlases.

The lice (Insecta: Phthiraptera) from Macquarie Island

Ricardo L. Palma and Donald S. Horning

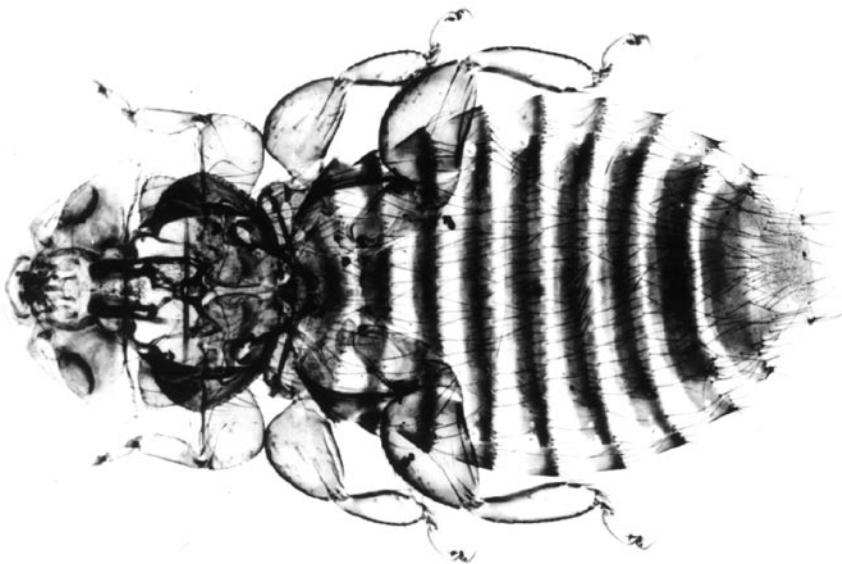

Abstract

Forty seven identified louse species from birds and mammals are listed from Macquarie Island. Five further records are given at the generic level only. Bibliographic references to Macquarie Island louse records are listed for each species and genus. A list of the host-louse associations is given.

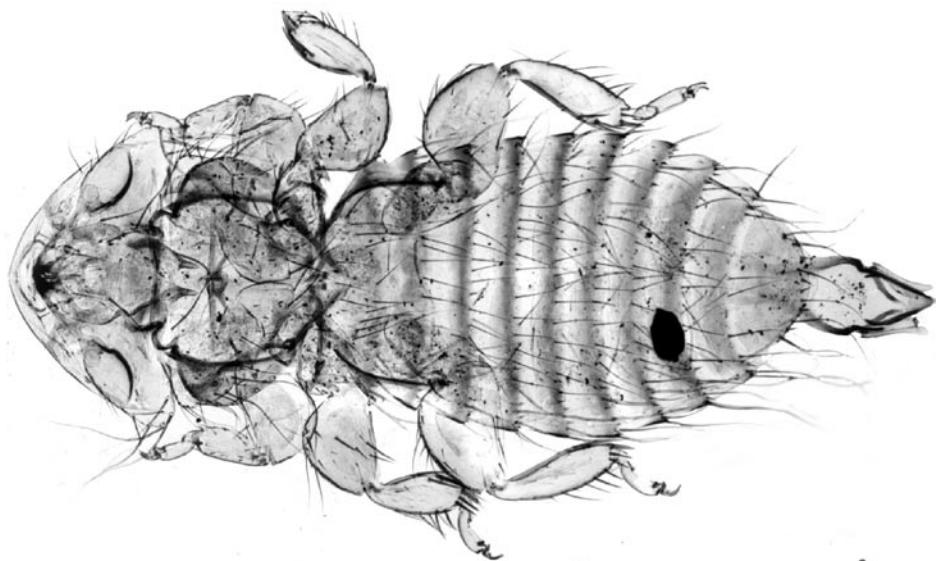

Introduction

When one sees Macquarie Island for the first time, it is hard not to think of it as a spectre, an isolated island ghostly rising out of the sea, mostly capped with a shroud of cloud. Halfway between the southern end of Tasmania and the Antarctic continent, Macquarie is located between 54°28' and 54°46'S, 148°50'E (Gressitt 1970). It is long and narrow, about 34 km by 2.5 to 5 km, situated in a nearly north - south direction and is 118 sq km in area. Most of the island consists of a plateau, with hills, tarns (small lake or large ponds), featherbeds (bryophyte-dominated quaking mire) and streams. The vegetation is low-growing and often sparse except along the coastlines and there are no trees on the island. The slopes rise steeply from beach terraces to the plateau. Their height ranges between 180 and 300 metres and their slope from 35 to 80° with an average slope of 43° (Horning 1978). It is a wild, isolated windswept island and thundered by predominantly westerly stormy seas. This isolation helps set the stage for a vast number of seabirds and marine mammals breeding and visiting Macquarie Island. There are 27 species of birds that breed or may breed on the island and 39 species have been recorded with some degree of vagrancy (common, occasional, rare, very rare) (Selkirk *et al.* 1990). There are three species of marine mammals breeding at Macquarie Island and four visiting species (Selkirk *et al.* 1990). All of these birds and marine mammals are potential hosts for lice.

The number of terrestrial invertebrate species is quite limited for an island of about 12,000 ha. Greenslade (1990) listed 78 species of terrestrial invertebrates (excluding parasites and mites) from Macquarie Island: 12 species of non-arthropods, 32 Collembola, 30 insects and 4 species of spiders. Greenslade and van Klinken (1994) listed 32 species of Collembola. In addition, recently, 25 species of Tardigrada (water bears) have been reported from the Island (Miller *et al.* 2001). This paper reports 47 species of lice, the largest, by far, of any insect group. The total of 150 recorded species of terrestrial invertebrates (excluding mites) is relatively low given the size of the island and its many habitats.

History of the Collections

The first lice known from Macquarie Island were collected by H. Hamilton, a biologist for the Australasian Antarctic Expedition, 1911-1914. He was on the island from 22 December 1911 to 28 November 1913. His main interests were collecting marine life, securing bird specimens and studying the plant life of the island. His collections of plants were the subject of a later study by S. Cheeseman (1919). He was also interested in the ecology of the flora (Hamilton 1926). Hamilton made a few collections of bird and mammal lice as opportunities afforded him. The only reference mentioning that he was looking for lice is found in Ainsworth (1996). Ainsworth was the leader of the Macquarie Island party and he stated in his narrative for 6 August 1912 "Hamilton secured some spiders, parasites on birds and many beetles under the moss and stones on the site of a penguin rookery, besides shooting a few terns". We have found no lice that were collected by him on that date, but sufficient specimens were collected in 1912 and 1913 for Harrison (1937) to report on these collections.

The next record of lice from the British, Australia and New Zealand Antarctic Research Expedition (BANZARE) shows that specimens were collected at least on 23 October 1929 and 4 December 1930. There was a gap of collecting until the Macquarie Island station was established by the Australian Antarctic Division in 1948. Sporadic collections have been made by ANARE (Australian National Antarctic Research Expeditions) personnel, The Australian Museum Macquarie Island Expedition during the summer 1977 and 1978, the Tasmanian National Parks and Wildlife Service and short-term visitors to the island. The years and primary collectors are: 1949, A.M. Gwynn; 1950, A.M Gwynn, N.M. Haydon, E. Shipp; 1953, J.B. Sturrock; 1955, K. Keith; 1956 - 1957 (many collectors); 1957, M.P. Hines, M.D. Murray; 1960 - 1961, J. Warham, K.C. Watson; 1962, W.J.M. Vestjens; 1965, C. Robertson; 1977-1978, G. Copson, D.S. Horning, J.K. Lowry, T. Tierney; 1984, N. Brothers, G. Copson; 1985, T. Scarborough; 1988, P. Sullivan.

Watson (1967) gave an account of the 38 species of lice known to that time, based primarily on collections by Hamilton and collections of the 1950's and early 1960's. Clay and Moreby (1970) recorded 26 species of lice from 14 species of birds without indication of the source of their information. Gressitt (1970) listed 36 species of bird and mammal lice but his records were extracted from the literature. Wise (1977) listed 38 species of lice from Macquarie Island and these records also came from previous literature. The catalogue of Palma and Barker (1996) is the most up-to-date and was primarily based on collection and literature records. We report 47 species of lice from Macquarie Island. Five further records are given at the generic level only. Previous erroneous records from the literature have been corrected as far as is possible (see Notes below).

Two hosts (sheep and weka) previously introduced by humans had lice recorded from them on Macquarie Island and have now been eradicated from the island (Copson 1995; Selkirk *et al.* 1990). These species of lice (*Bovicola (Bovicola) ovis* and *Rallicola harrisoni*) are no longer part of the island fauna.

Remarks

The louse list includes all the genera and species recorded from Macquarie Island. Under each species we have listed all the bibliographic citations referring to that island, but giving first the original taxonomic combination which, in most cases, refers to other localities. Species marked with an asterisk are from non-breeding hosts. Species names given in quotations (" ") are misidentifications by the authors cited immediately after the closing quotations.

Location of specimens: Early collections of Macquarie Island lice are held in the British Museum (Natural History), London, England, and the Australian Museum, Sydney. More recently collected samples are kept in the Australian National Insect Collection, Canberra; the Museum of New Zealand Te Papa Tongarewa, Wellington; the Queen Victoria Museum and Art Gallery, Launceston, Tasmania and in the United States National Museum of Natural History, Washington.

Lice recorded from Macquarie Island

Order PHTHIRAPTERA Haeckel, 1896

Suborder AMBLYCERA Kellogg, 1896

Family MENOPONIDAE Mjöberg, 1910

Host: *Mirounga leonina*.

Macquarie Island Host – Lice Associations

Most of the hosts listed below are known to be parasitised by further louse species in other localities (see Pilgrim and Palma 1982; Palma and Barker 1996). More intensive collecting will no doubt reveal the true number of louse species living on Macquarie Island hosts. Louse entries qualified as “stragglers” are the result of natural or human contamination, and we do not regard them as regular host-louse associations.

*Denotes louse species recorded from hosts which do not breed on Macquarie Island.

Class Aves

The sequence and nomenclature of species and subspecies of birds follow the Ornithological Society of New Zealand (1990) Checklist.

Order Procellariiformes

Diomedea exulans Linnaeus, 1758

wandering albatross

Docophoroides brevis (Dufour, 1835)

Harrisoniella hopkinsi Eichler, 1952

Paraclisis hyalina (Neumann, 1911)

Naubates pterodromi Bedford, 1930 sensu lato [straggler]

Diomedea melanophrys melanophrys Temminck, 1828

black-browed mollymawk

Paraclisis diomedae (J.C. Fabricius, 1775)

Perineus circumfasciatus Kéler, 1957

Diomedea chrysostoma Forster, 1785

grey-headed mollymawk

Docophoroides simplex (Waterston, 1914)

Paraclisis diomedae (J.C. Fabricius, 1775)

Phoebetria palpebrata (Forster, 1785)

light-mantled sooty mollymawk

Paraclisis diomedae (J.C. Fabricius, 1775)

Perineus circumfasciatus Kéler, 1957

Puffinus griseus (Gmelin, 1789)

sooty shearwater

Halipeurus (Halipeurus) diversus (Kellogg, 1896)

Trabeculus hexakon (Waterston, 1914) sensu lato

Naubates prioni (Enderlein, 1908) [straggler]

Puffinus tenuirostris (Temminck, 1835)

short-tailed shearwater

* *Halipeurus (Halipeurus) diversus* (Kellogg, 1896)

Pelecanoides urinatrix exsul Salvin, 1896

Subantarctic diving petrel

Pelmatocerandra setosa (Giebel, 1876)

<i>Procellaria cinerea</i> Gmelin, 1789	grey petrel
<i>Naubates fuliginosus</i> (Taschenberg, 1882)	
<i>Trabeculus hexakon</i> (Waterston, 1914) <i>sensu lato</i>	
<i>Halipeurus (Halipeurus) procellariae</i> (J.C. Fabricius, 1775) [straggler]	
<i>Daption capense</i> (Linnaeus, 1758)	Cape pigeon
* <i>Pseudonirmus gurtli</i> (Taschenberg, 1882)

<i>Austrogoniodes hamiltoni</i> Harrison, 1937	
<i>Austrogoniodes macquariensis</i> Harrison, 1937	
<i>Eudyptes chrysolophus schlegeli</i> Finsch, 1876	royal penguin
<i>Austrogoniodes cristati</i> Kéler, 1952	
<i>Austrogoniodes hamiltoni</i> Harrison, 1937	
<i>Austrogoniodes macquariensis</i> Harrison, 1937	
<i>Eudyptes robustus</i> Oliver, 1953	Snares crested penguin
* <i>Austrogoniodes macquariensis</i> Harrison, 1937 [straggler]	
* <i>Austrogoniodes hamiltoni</i> Harrison, 1937 [straggler]	
<i>Eudyptes sclateri</i> Buller, 1888	erect-crested penguin
* <i>Austrogoniodes cristati</i> Kéler, 1952	

Order Pelecaniformes

<i>Leucocarbo atriceps purpurascens</i> (Brandt, 1837)	Macquarie Island shag
<i>Pectinopygus turbinatus</i> (Piaget, 1890)	

Order Anseriformes

<i>Anas superciliosa superciliosa</i> Gmelin, 1789	grey duck
<i>Anaticola crassicornis</i> (Scopoli, 1763)	
<i>Anatoecus dentatus</i> (Scopoli, 1763)	

Order Gruiformes

<i>Gallirallus australis scotti</i> (Ogilvie-Grant, 1905)	Stewart Island weka
<i>Rallicola harrisoni</i> Emerson, 1955	

Order Charadriiformes

<i>Calidris canutus canutus</i> (Linnaeus, 1758)	lesser knot
* <i>Saemundssonia</i> (<i>Saemundssonia</i>) sp.	
<i>Catharacta skua lonnbergi</i> Mathews, 1912	Subantarctic skua
<i>Austromenopon fuscofasciatum</i> (Piaget, 1880)	
<i>Haffneria grandis</i> (Piaget, 1880)	
<i>Saemundssonia</i> (<i>Saemundssonia</i>) <i>euryrhyncha</i> (Giebel, 1874)	

<i>Larus dominicanus</i> Lichtenstein, 1823	southern black-backed gull
<i>Actornithophilus piceus lari</i> (Packard, 1870)	
<i>Quadraceps ornatus fuscolaminulatus</i> (Enderlein, 1908)	

Saemundssonia (Saemundssonia) lari (O. Fabricius, 1780)
Naubates prioni (Enderlein, 1908) [straggler]

***Sterna vittata bethunei* Buller, 1896** New Zealand Antarctic tern

Quadraceps houri Hopkins, 1949
Saemundssonia (Saemundssonia) lockleyi Clay, 1949

Class Mammalia

Order Pinnipedia

***Hydrurga leptonyx* (de Blainville, 1820)** leopard seal
Antarctophthirus ogmorrhini Enderlein, 1906

***Mirounga leonina* (Linnaeus, 1758)** southern elephant seal
Lepidophthirus macrorhini Enderlein, 1904

Order Artiodactyla

Ovis aries Linnaeus, 1758 sheep
Bovicola (Bovicola) ovis (Schrank, 1781)

Order Rodentia

***Rattus rattus* (Linnaeus, 1758)** black rat
Polyplax spinulosa (Burmeister, 1839)

Potential Host Species with no records of Lice

There are breeding species which are potential hosts for lice, but they have not been searched for or found to have lice on Macquarie Island as yet. Three bird species (+) are listed in Selkirk et al. (1990) as “rare, may breed” and these should be examined for lice as opportunities occur. The potential hosts are:

<i>Pachyptila turtur</i> (Kuhl, 1820)	fairy prion
+<i>Pachyptila belcheri</i> (Mathews, 1912)	thin-billed prion
+<i>Pterodroma mollis</i> (Gould, 1841)	soft-plumaged petrel
+<i>Oceanites nereis</i> (Gould, 1840)	grey-backed storm petrel
<i>Pygoscelis papua papua</i> (Forster, 1781)*	northern gentoo penguin
<i>Anas platyrhynchos</i> Linnaeus, 1758	mallard
<i>Sturnus vulgaris</i> Linnaeus, 1758	starling
<i>Carduelis flammea</i> (Linnaeus, 1758)	redpoll
<i>Arctocephalus gazella</i> (Peters, 1875)	Antarctic fur seal
<i>Arctocephalus tropicalis</i> (Gray, 1872)	Subantarctic fur seal
<i>Oryctolagus cuniculus</i> (Linnaeus, 1758)	rabbit
<i>Mus musculus</i> Linnaeus, 1758	house mouse
<i>Felis catus</i> Linnaeus, 1758	feral cat

* The single louse collected from this host is a straggler or contaminant.

Discussion

We list and document 47 species of lice – plus five records at the generic level only – from Macquarie Island. They were collected from 24 species of breeding (some not confirmed) hosts and from eight species of vagrant hosts. These data are comparable to those from a very small cool temperate island group, The Snares (usually regarded as a New Zealand subantarctic island), where 53 species of lice were recorded from 18 species of breeding hosts and 11 species of vagrants (Horning *et al.* 1980).

There were significant differences in the collecting techniques between the two islands. At Macquarie, lice collections were primarily adventitious when opportunities arose. It also appears that almost all collections resulted from hand-searching of live or dead birds. Hand-searching is an unintentionally selective technique and consequently some lice species will have been overlooked, especially in less common hosts (see Horning *et al.* 1980: 14). At The Snares, there was a concerted effort to collect lice by hand-searching alive and dead birds but also by dusting live hosts with the insecticide 'Dri-Die' over a white tray or sheet, or by dissolving feathers of recent or long-dead birds in hot 15% potassium hydroxide (Horning *et al.* 1980). Furthermore, collectors between 1961 and 1971, the period in which the lice were collected, were well trained in the recognition of the breeding bird species.

There is a large number of straggler louse species from Macquarie Island (see Notes 3, 4, 5, 6, 7, 8, 9, 11, 12, 14, 16, 17 and 24). We believe that, in fact, some of these records are not stragglers but stem from misidentification of the hosts. Sometimes lice were collected from parts of a bird (mainly wings) lying on the ground or from skua middens. To the untrained eye, it is difficult to identify parts of birds, especially petrels and prions. On the other hand, it is possible that some of these lice were stragglers. For instance, white-headed petrels are occasionally found with sooty shearwaters; fairy prions may compete with blue petrels for nesting burrows; blue petrels occupy diving petrel burrows (Selkirk *et al.* 1990). These 'close encounters' between individuals of different host species are ideal opportunities for lice to straggle. However, since breeding colonies of birds, with the exception of penguins, are scattered over the island and are not crowded with several species, we believe most of the host-louse associations we regard here as the result of natural straggling or human contamination (mixing samples during collecting, mislabelling vials or misidentifications of hosts) belong most likely to the latter category. The situation at The Snares is very different, where there are enormous populations of breeding sea birds and two or three species may use a common burrow entrance. We believe that opportunities for lice to straggle at The Snares, where Horning *et al.* (1980) recorded 14 straggling louse species, are greater than at Macquarie. Also the likelihood of human contamination was far lower at The Snares than at Macquarie Island.

Notes

1. In the Australian Museum collection there are a male and a female *Austrogoniodes* from *Eudyptes chrysolophus schlegeli* which Harrison (1937: 15) recorded as *A. strutheus*. We have examined and identified them as *Austrogoniodes cristati*. The dubious taxonomic status of *Austrogoniodes strutheus* was discussed by Clay (1967: 153), and there has not been further change since that publication.
2. The single female *Austrogoniodes* from *Eudyptes sclateri* recorded by Harrison (1937: 15) as *A. waterstoni* is kept in the Australian Museum collection. Pilgrim and Palma (1982: 5, 29) regarded Harrison's record as a straggler because they had not examined the specimen. We have examined the single female and identified it as *Austrogoniodes cristati*. Therefore, it is not a straggler on *E. sclateri*.
3. As noted by Pilgrim and Palma (1982: 5, 29), the records of *Austrogoniodes hamiltoni* and *A. macquariensis* from *Eudyptes robustus* in Watson (1967: 71, as *Eudyptes pachyrhynchus atratus*) are the result of natural or human contamination from either *E. c. schlegeli* or *E. chrysocome filholi*.
4. Watson (1967: 72) recorded *Halipeurus turtur* from *Pachyptila desolata* collected by ANARE, 1949, but without specifying the number or sex of the specimens. In the British Museum (Natural History) there is a male bearing identical data which we have examined and identified as *Halipeurus (H.) diversus*. The only regular host known for *H. (H.) turtur* is *Pterodroma cookii* (see Pilgrim and Palma 1982: 9).
5. No species of *Pachyptila* is known to be a regular host to any species of *Halipeurus* (see Pilgrim and Palma 1982: 10, 11; Palma and Barker 1996: 343). We regard the record of *H. (H.) diversus* on *P. desolata* as the result of natural or human contamination from *Puffinus griseus* or *P. tenuirostris*.
6. Pilgrim and Palma (1982: 30) examined and corrected the identification of the single female *Halipeurus* recorded as *Halipeurus angusticeps* by Harrison (1937: 31) and kept in the Australian Museum collection. It is *Halipeurus (H.) procellariae*.
7. No species of *Procellaria* is known to be a regular host to any species of *Halipeurus* (see Pilgrim and Palma 1982: 11; Palma and Barker 1996: 344). We regard the record of *H. (H.) procellariae* on *P. cinerea* as the result of natural or human contamination from *Pterodroma lessonii*.
8. Among the lice collected during the summer 1977-1978 by the Australian Museum Macquarie Island Expedition, there is a female *Naubates clypeatus* from *Pachyptila desolata banksi*. We regard this record as a straggler or contaminant from *Halobaena caerulea*, the only regular host known for *N. clypeatus* (see Pilgrim and Palma 1982: 9, 10).
9. As noted by Pilgrim and Palma (1982: 8, 30), *Pterodroma lessonii* is an erroneous host for *Naubates heteroproctus*, despite being its type host. The regular host for *N. heteroproctus* is *Pterodroma macroptera*. Our inclusion of *N. heteroproctus* in the Macquarie Island fauna is therefore based on Harrison's type material only. Subsequent authors have listed *N. heteroproctus* following Harrison (1937: 30).
10. Harrison (1937: 31) recorded *Naubates clypeatus* from *Pachyptila desolata banksi* (as *Prion desolatus*) based on two specimens collected from a skin in the Australian Museum. Those specimens have not been located despite intensive search by the

Australian Museum staff, but we are confident that they were *Naubates prioni*, the species of *Naubates* widespread on all species and subspecies of *Pachyptila* (see Pilgrim and Palma 1982: 10, 11). Harrison (1916: 132, 140) had already synonymised *N. prioni* under *N. clypeatus*, and therefore it is logical to assume that he identified further *Naubates* material accordingly.

11. Watson (1967: 72) recorded a single female *Naubates* sp. from *Pygoscelis papua* as a probable straggler from one of the petrels. In the Australian National Insect Collection there is a female bearing identical data which we have examined and identified as *Naubates prioni*. We regard it as a straggler or contaminant from a *Pachyptila* host.
12. Further to the record of *Naubates prioni* discussed above, the Australian National Insect Collection has nine specimens of *Naubates prioni*, one from *Puffinus griseus* and eight from *Larus dominicanus*, which we also regard as stragglers or contaminants from a *Pachyptila* host.
13. Several records of *Naubates heteroproctus* from *Pterodroma lessonii* are either misidentifications of *N. pterodromi sensu lato*, or a combination of *N. pterodromi sensu lato* and Harrison's type material of *N. heteroproctus* (see also Note 9, above).
14. Clay and Moreby (1970: 217) listed *Naubates fuliginosus* under *Diomedea exulans*. In the Australian National Insect Collection there is a male and female pair *Naubates* from that host which we have examined and identified as *Naubates pterodromi sensu lato*. No species of *Diomedea* is known as a regular host of any *Naubates* lice (see Pilgrim and Palma 1982: 5-7), therefore we regard this record as the result of natural or human contamination from *Pterodroma lessonii*. Subsequent authors have listed *N. fuliginosus* following Clay and Moreby's misidentification.
15. Among the lice collected during the summer 1977-1978 by the Australian Museum Macquarie Island Expedition, there is a single nymph of *Pseudonirmus* from *Thalassoica antarctica* which, at present, we can not identify to species.
16. We agree with Pilgrim and Palma (1994: 242) in regarding *Fulmarus glacialisoides* as a non-regular host for *Saemundssonia (S.) antarctica*.
17. We regard the single male *Saemundssonia (S.) bicolor* collected from *Thalassoica antarctica* by the Australian Museum Macquarie Island Expedition as a straggler or contaminant from a *Fulmarus glacialisoides* host (see Pilgrim and Palma 1982: 7; 1994: 242).
18. In the Australian Museum collection there are a male and a female *Saemundssonia* from *Larus dominicanus* which Harrison (1937: 21) recorded as *Philopterus gonothorax*. We have examined and identified them as *Saemundssonia (S.) lari*, a name we regard as a senior synonym of *Philopterus gonothorax*, as published by Ledger (1980: 139).
19. Watson (1967: 74) recorded *Saemundssonia* sp. from *Larus dominicanus* collected by W.J.M. Vestjens in 1962. In the Australian National Insect Collection there is a slide bearing identical data which we have examined and identified as *Saemundssonia (S.) lari*.
20. Harrison (1937: 22) recorded *Philopterus melanocephalus* from *Sterna vittata bethunei* (as *Sterna* sp.) based on a series collected by H. Hamilton in 1912. No specimen of that series has been located despite intensive search by the Australian

Museum staff, but we are confident that they were *Saemundssonia* (*S.*) *lockleyi*, the species of *Saemundssonia* regularly found on *Sterna vittata bethunei* (see Pilgrim and Palma 1982: 23; Palma and Barker 1996: 223). Watson (1967: 74) listed the same material as *Saemundssonia* sp. Further collections have confirmed the presence of *Saemundssonia* (*S.*) *lockleyi* on *Sterna vittata bethunei* from Macquarie Island.

21. Watson (1967: 74) recorded *Saemundssonia* sp. from *Catharacta skua lonnbergi* collected by W.J.M. Vestjens in 1962. In the Australian National Insect Collection there are specimens with identical data which we have examined and identified as *Saemundssonia* (*S.*) *euryrhyncha*.
22. Harrison (1937: 21) recorded *Philopterus limosae* from *Calidris canutus* (as “an undetermined *Limicoline*”) based on a single male collected by H. Hamilton in 1913. That male has not been located despite intensive search by the Australian Museum staff. Watson (1967: 74) listed the same record as *Saemundssonia* sp. Considering our poor knowledge on *Saemundssonia* from *Calidris canutus*, we prefer to leave this record at the generic level only (see also Pilgrim and Palma 1982: 21, 31).
23. Watson (1967: 74) recorded *Saemundssonia* sp. from *Pterodroma lessonii* collected by ANARE in 1949. Although we have not been able to examine that sample or any other from Macquarie Island, numerous further collections of *Saemundssonia* from *Pterodroma lessonii* in many localities, belong to the species *Saemundssonia* (*Puffinoecus*) *enderleini* (Eichler, 1949).
24. Harrison (1937: 37) recorded *Giebelia hexakon* from *Pachyptila desolata banksi* (as “*Prion* sp., ?*vittatus*”) based on a female and a nymph collected by H. Hamilton in 1912. Those specimens have not been located despite intensive search by the Australian Museum staff. Kéler (1952: 205) mentioned Harrison’s record without further comment, and Watson (1967: 74) listed the same record as *Trabeculus* sp. No species of *Pachyptila* is known to be a regular host to any species of *Trabeculus* (see Pilgrim and Palma 1982: 10, 11; Palma and Barker 1996: 343). Hence, we consider this record as the result of natural or human contamination, as well as an unidentifiable species.
25. Harrison (1937: 13) recorded *Menopon* sp. from *Diomedea exulans* and from *Pachyptila desolata banksi* (as “*Prion vittatus*”) based on 2 immature specimens collected in 1913 and 1912 respectively. Those specimens have not been located despite intensive search by the Australian Museum staff. Based on the louse species known from these 2 hosts (see Pilgrim and Palma 1982: 5, 10), we can assume that they were nymphs of *Austromenopon* but, in the absence of the actual material, we prefer to leave these records at the generic level only.

Acknowledgements: As so aptly put by Orchard (1986) “The gestation period of this paper makes elephants look like fast breeders.” This is the sole responsibility of the second author, DSH. Many people have contributed ideas and suggestions through the years and it is not possible to list them all. We are most grateful to Dr M.D. Murray (Sydney, Australia) and Professor R.L.C. Pilgrim (Christchurch, New Zealand) for fruitful discussion as well as for providing identifications and locating data of early collections of Macquarie Island lice. We thank Geoff Copson (Department of Primary Industries, Water and Environment, Hobart, Tasmania), for providing references and literature. The following people have been most helpful in obtaining collection information:

Dr C. Lyal (The Natural History Museum, London); Dr D. Colless (Australian National Insect Collection, Canberra); G. Holloway (Australian Museum, Sydney). The Australian Museum Trust is acknowledged for providing funds for the 1977-1978 Macquarie Island Expedition. Without its support, this paper would have never been brought to fruition.
